# Reduction to normal form of a self-adjoint linear transformation with respect to a pseudo-unitary or a pseudo-euclidean inner product 

Shahla Ahdout<br>Sheldon Rothman<br>Long Island University, USA

#### Abstract

We provide a self-contained and constructive approach to reduce a self-adjoint linear transformation defined on a pseudo-unitary (resp., pseudoeuclidean) space to a canonical form.

Keywords and phrases. Pseudo-unitary, pseudo-euclidean, self-adjoint, orthogonal.

2000 Mathematics Subject Classification. Primary: 15A21. Secondary: 15A57.

Resumen. Nosotros damos una aproximación auto-contenida y constructiva para reducir una transformación lineal auto-adjunta definida sobre un espacio pseudo-unitario (resp. pseudo-euclidiano) a una forma canónica.

## 1. Introduction

Using pencils of matrices the simultaneous reduction of a pair of real symmetric matrices to a normal form was first developed by Weierstrass [9] and Kronecker [4]. Since then several authors, e.g., [2], [6], and [8], have studied the canonical forms for a pair of structured matrices. In this paper, we show that a complex (resp. real) self-adjoint linear transformation on a pseudo-unitary (resp. pseudo-euclidean) space can be brought to a canonical form via a basis that is orthonormal with respective to the inner product. Following a different approach than the authors mentioned above, we provide an explicit construction that produces an orthonormal basis relative to which the given linear transformation has a canonical form. In the complex case, the orthonormal basis is a modification of a Jordan basis, whereas in the real case, our basis will be a modification of a basis associated with the real Jordan form.

We are very grateful to the referee for making a number of useful remarks and suggestions that significantly helped to improve the final version of the paper.

## 2. Definitions and preliminaries

A complex linear space $E$ of dimension n is called pseudo-unitary if there is a non-degenerate, indefinite, Hermitian form defined on it. This form is called an inner product and is denoted by $\langle$,$\rangle . When the inner product is positive$ definite then the space $E$ is simply a unitary space. We denote $\|x\|=\langle x, x\rangle$ and call it the norm of $x$. Two vectors $x$ and $y$ in $E$ are called orthogonal if $\langle x, y\rangle=0$. A basis $\left\{e_{i}\right\},(1 \leq i \leq n)$ is called an orthonormal basis if for some $p, 1 \leq p \leq n$,

$$
\left\langle e_{i}, e_{i}\right\rangle=\left\{\begin{aligned}
1 & \text { for } 1 \leq i \leq p \\
-1 & \text { for } p+1 \leq i \leq n
\end{aligned}\right.
$$

and $\left\langle e_{i}, e_{j}\right\rangle=0$ for $i \neq j$.
Given a pseudo-unitary space, it is well known that an orthonormal basis $\left\{e_{i}\right\}$ can always be constructed and that $p$ is a fixed number, ([3]; 9.8, pp. 267-8). In this basis, if we write $v=\sum_{i=1}^{n} v_{i} e_{i}$ and $w=\sum_{i=1}^{n} w_{i} e_{i}$ then

$$
\langle v, w\rangle=v_{1} \bar{w}_{1}+v_{2} \bar{w}_{2}+\cdots+v_{p} \bar{w}_{p}-v_{p+1} \bar{w}_{p+1}-\cdots-v_{n} \bar{w}_{n} .
$$

A linear transformation, T , on $E$ is called self-adjoint if $\langle T x, y\rangle=\langle x, T y\rangle$. When $E$ is a unitary space, T is called symmetric.

We now make analogous definitions for a real vector space. A real ndimensional vector space, V , is called pseudo-euclidean if there is a non-degenerative, indefinite, symmetric bilinear form defined on it. As before, we call this bilinear form an inner product and denote it by $\langle$,$\rangle . When the inner product is positive$ definite the space is a euclidean space. Orthogonal vectors, norm, orthonormal basis, and self-adjoint linear transformations are defined as above. Again, it is well known that an orthonormal basis exists ([3]; 9.8, pp. 267-8). If $\left\{e_{i}\right\}$ is an orthonormal basis of V , and if $x=\sum_{i=1}^{n} x_{i} e_{i}, y=\sum_{i=1}^{n} y_{i} e_{i}$, then

$$
\langle x, y\rangle=x_{1} y_{1}+x_{2} y_{2}+\cdots+x_{p} y_{p}-x_{p+1} y_{p+1}-\cdots-x_{n} y_{n}
$$

In Section 3, we consider a self-adjoint, linear transformation $T$ acting on a pseudo-unitary space $E$. Our goal is to construct an orthonormal basis of $E$ such that the matrix of $T$ with respect to this basis is of a normal form. We begin by showing that $E$ is a direct sum of invariant, mutually orthogonal subspaces where the restriction of $T$ to each subspace has either a single real or a single pair of complex conjugate eigenvalues. This will essentially reduce our problem to two cases: (1) $T$ has a single real eigenvalue, and (2) $T$ has a single pair of complex conjugate eigenvalues. In each of these cases, a modification of the standard Jordan basis produces the desired orthonormal basis.

In Section 4 we consider a self-adjoint linear transformation acting on a pseudo-euclidean space. Here again, we show that our vector space is a direct
sum of invariant, mutually orthogonal subspaces where the restriction of $T$ to each subspace has either a single real or a single pair of complex conjugate eigenvalues, and this reduces the problem to the two cases mentioned above. If an eigenvalue is real we use the usual Jordan basis. Otherwise, we use the basis corresponding to the real Jordan form for a complex eigenvalue.

Below are a number of types of matrices that will be used throughout the paper. An omitted entry in a matrix is meant to be the entry ' 0 '. The superscript "F" refers either to $r=$ the field of real numbers or to $c=$ the field of complex numbers. For a matrix $A, A^{*}$ will denote its negative transpose. The matrix $I_{n}$ is the identity matrix of dimension $n$.

The following are square matrices:

$$
\begin{aligned}
& \left(A_{y}\right)^{F}(x)=\left[\begin{array}{cccc}
x & \frac{1}{2} & & \\
\frac{1}{2} & \ddots & \ddots & \\
& \ddots & x & \frac{1}{2} \\
& & \frac{1}{2} & x+\frac{y}{2}
\end{array}\right] \quad\left(\widehat{A}_{y}\right)^{F}(x)=\left[\begin{array}{cccc}
x & -\frac{1}{2} & & \\
\frac{1}{2} & \ddots & \ddots & \\
& \ddots & x & -\frac{1}{2} \\
& & \frac{1}{2} & x+\frac{y}{2}
\end{array}\right] \\
& B^{F}(x)=\left[\begin{array}{cccc}
x & \frac{1}{2} & & \\
\frac{1}{2} & \ddots & \ddots & \\
& \ddots & x & \frac{1}{\sqrt{2}} \\
& & \frac{1}{\sqrt{2}} & x
\end{array}\right] \quad\left({ }^{y} A\right)^{F}(x)=\left[\begin{array}{cccc}
x+\frac{y}{2} & \frac{1}{2} & & \\
\frac{1}{2} & x & \ddots & \\
& & \ddots & \ddots
\end{array} \frac{1}{2}\right.
\end{aligned}
$$

$$
\begin{aligned}
& M^{r}(\alpha)=\left[\begin{array}{ccccc}
x & \frac{1}{\sqrt{2}} & & & \\
\frac{1}{\sqrt{2}} & \ddots & \frac{1}{2} & & \\
& \frac{1}{2} & \ddots & \ddots & \\
& & \ddots & \ddots & \frac{1}{2} \\
& & & \frac{1}{2} & x
\end{array}\right] .
\end{aligned}
$$

When $x=0$ or $y=0$ we simply drop the zero, e.g., we write $\left(A_{y}\right)^{F}$ for $\left(A_{y}\right)^{F}(0)$ and $A^{F}(x)$ for $\left(A_{0}\right)^{F}(x)$.

The following matrices are of dimension $l \times(l+1)$ :

$$
\widehat{K}^{F}=\left[\begin{array}{rcccc} 
& & -\frac{1}{2} & & \\
& \frac{1}{2} & & \ddots & \\
& & \ddots & & -\frac{1}{2} \\
-\frac{1}{\sqrt{2}} & & & \frac{1}{2} &
\end{array}\right] \widehat{E}=\left[\begin{array}{lllll} 
& & & -\frac{1}{2} & \\
& & . & & \frac{1}{2} \\
& -\frac{1}{2} & & . & \\
-\frac{1}{\sqrt{2}} & & \frac{1}{2} & &
\end{array}\right]
$$

The following matrices are of dimension $(l+1) \times l$ :

$$
\begin{aligned}
G^{F}(x) & =\left[\begin{array}{cccc}
\frac{1}{\sqrt{2}} & & & \\
x & \frac{1}{2} & & \\
\frac{1}{2} & \ddots & \ddots & \\
& \ddots & \ddots & \frac{1}{2} \\
& & \frac{1}{2} & x
\end{array}\right] \quad \widehat{C}^{F}=\left[\begin{array}{cccc} 
& -\frac{1}{2} & & \\
\frac{1}{2} & & \ddots & \\
& \ddots & & -\frac{1}{2} \\
& & \frac{1}{2} & \frac{1}{\sqrt{2}}
\end{array}\right] \\
\widehat{N}^{r} & =\left[\begin{array}{cccc} 
& & \frac{1}{2} & \\
& . & & \frac{1}{2} \\
-\frac{1}{2} & & . & \\
\frac{1}{\sqrt{2}} & \frac{1}{2} & &
\end{array}\right] .
\end{aligned}
$$

## 3. Self-adjoint linear transformations on a pseudo-unitary Space

Let $E$ be a pseudo-unitary space and let $T$ be a self-adjoint linear transformation on $E$. It is known (See [1], Theorem 3.3, pp. 35) if $\alpha \neq \bar{\beta}$ are eigenvalues of $T$ then the corresponding eigenspaces $E_{\alpha}$ and $E_{\beta}$ are perpendicular. This along with non-degeneracy of the inner product implies that complex eigenvalues of $T$ appear in complex conjugate pairs, and we can decompose $E$ into a direct sum of invariant and pairwise orthogonal subspaces

$$
E=E_{1}+\cdots+E_{s}
$$

where each $E_{i}$ is either an eigenspace of $T$ corresponding to a real eigenvalue or is the sum of eigenspaces corresponding to a single pair of complex conjugate eigenvalues. Therefore, our study of the transformation $T$, is reduced to its action on each subspace $E_{p}$. We consider two cases.

## Case I: $T$ has a single real eigenvalue.

The next lemma shows that a particular kind of Jordan basis can be chosen on each subspace $E_{p}$.

Lemma 3.1. Let $T$ be a self-adjoint, linear transformation on the pseudounitary space $E$, with a single real eigenvalue $\alpha$. Then, $E$ can be decomposed into the direct sum of pairwise orthogonal, invariant subspaces, $E=E_{1}+E_{2}+$ $\cdots+E_{t}$, where the restriction of $T$ to each subspace produces a Jordan block. The Jordan basis

$$
v_{1}=v, \quad v_{2}=(T-\alpha I) v_{1}, \quad \cdots, v_{k}=(T-\alpha I) v_{k-1}
$$

for an orthogonal subspace $E_{p}$ can be chosen such that

$$
\left\langle v_{i}, v_{j}\right\rangle=\left\langle v_{1}, v_{k}\right\rangle=\epsilon \quad \text { if } \quad i+j=k+1,
$$

where $\epsilon= \pm 1$ and

$$
\left\langle v_{i}, v_{j}\right\rangle=0 \quad \text { if } \quad i+j \neq k+1
$$

(Note: The sign of $\left\langle v_{1}, v_{k}\right\rangle$, known as the sign characteristic of the inner product on $E_{p}$ is determined by the transformation $T$ and cannot be changed.)

Proof. See [5] page 244.
Next we construct an orthonormal basis for each $E_{p}$.
Proposition 3.1. Let $E_{p}$ be an invariant subspace of $E$ with associated real eigenvalue $\alpha$ as in Lemma 3.1. Then the Jordan basis given in this lemma can be modified to get an orthonormal basis $\beta$ of $E_{p}$ such that the matrix of $T$ with respect to $\beta$ is
a) for $k=2 l$ even

$$
\left[\begin{array}{cc}
\left(A_{\epsilon}\right)^{r}(\alpha) & \left(\widehat{A}_{\epsilon}\right)^{r} \\
\left(\left(\widehat{A}_{\epsilon}\right)^{r}\right)^{*} & \left(A_{-\epsilon}\right)^{r}(\alpha)
\end{array}\right] .
$$

(Each block is of dimension l).
b) for $k=2 l+1$ odd and the sign characteristic is positive

$$
\left[\begin{array}{cc}
B^{r}(\alpha) & \widehat{C}^{r} \\
\left(\widehat{C}^{r}\right)^{*} & A^{r}(\alpha)
\end{array}\right] .
$$

( $B^{r}(\alpha)$ is of dimension $l+1, A^{r}(\alpha)$ is of dimension $\left.l\right)$.
c) for $k=2 l+1$ odd and the sign characteristic is negative

$$
\left[\begin{array}{cc}
A^{r}(\alpha) & \widehat{K}^{r} \\
\left(\widehat{K}^{r}\right)^{*} & L^{r}(\alpha)
\end{array}\right] .
$$

( $A^{r}(\alpha)$ is of dimension $l, L^{r}(\alpha)$ is of dimension $\left.l+1\right)$.
Proof. Suppose $k=2 l$ is even and the sign characteristic is positive. Then the following is an orthonormal basis

$$
a_{1}=\frac{1}{\sqrt{2}}\left(v_{1}+v_{2 l}\right), \quad a_{2}=\frac{1}{\sqrt{2}}\left(v_{2}+v_{2 l-1}\right), \cdots, a_{l}=\frac{1}{\sqrt{2}}\left(v_{l}+v_{l+1}\right)
$$

$$
a_{l+1}=\frac{1}{\sqrt{2}}\left(v_{1}-v_{2 l}\right), \quad a_{l+2}=\frac{1}{\sqrt{2}}\left(v_{2}-v_{2 l-1}\right), \cdots, a_{2 l}=\frac{1}{\sqrt{2}}\left(v_{l}-v_{l+1}\right) .
$$

(If the sign characteristic is negative, replace $a_{i}$ by $a_{l+i}$, and viceversa for $1 \leq i \leq l)$.

If $\mathrm{k}=2 l+1$ is odd and the sign characteristic is positive, then the orthonormal basis is

$$
\begin{gathered}
a_{1}=\frac{1}{\sqrt{2}}\left(v_{1}+v_{2 l+1}\right), \quad a_{2}=\frac{1}{\sqrt{2}}\left(v_{2}+v_{2 l}\right), \cdots, a_{l}=\frac{1}{\sqrt{2}}\left(v_{l}+v_{l+2}\right) \\
a_{l+1}=v_{l+1} \\
a_{l+2}=\frac{1}{\sqrt{2}}\left(v_{1}-v_{2 l+1}\right), \quad a_{l+3}=\frac{1}{\sqrt{2}}\left(v_{2}-v_{2 l}\right), \cdots, a_{2 l+1}=\frac{1}{\sqrt{2}}\left(v_{l}-v_{l+2}\right) .
\end{gathered}
$$

(If the sign characteristic is negative, replace $a_{i}$ by $a_{l+1+i}$, and viceversa for $1 \leq i \leq l)$.

## Case II: T has a single pair of complex conjugate eigenvalues.

Lemma 3.2. Let $T$ be a self-adjoint, linear transformation on the pseudounitary space $E$ with a single pair of complex conjugate eigenvalues $\lambda$ and $\bar{\lambda} . E$ can be decomposed into a direct sum of orthogonal invariant subspaces, $E=E_{1}+\cdots+E_{r}$, where the restriction of $T$ to each subspace produces a pair of Jordan blocks. Jordan bases for a subspace $E_{p}$ can be chosen such that

$$
\begin{gathered}
v_{1}=v, \quad v_{2}=(T-\lambda I) v_{1}, \cdots, v_{k}=(T-\lambda I) v_{k-1} \\
w_{1}=w, \quad w_{2}=(T-\bar{\lambda} I) w_{1}, \cdots, w_{k}=(T-\bar{\lambda} I) w_{k-1},
\end{gathered}
$$

where

$$
\left\langle v_{i}, w_{j}\right\rangle=\left\langle v_{k}, w_{1}\right\rangle=1 \quad \text { if } \quad i+j=k+1
$$

and

$$
\left\langle v_{i}, w_{j}\right\rangle=0 \quad \text { if } \quad i+j \neq k+1 .
$$

Proof. See [5] page 242.
Proposition 3.2. Let $E_{p}$ be an invariant orthogonal component with a complex eigenvalue $\lambda$ as in Lemma 3.2 and let $\lambda=a+b i, b>0$. The Jordan basis defined above can be modified to obtain an orthonormal basis of $E_{p}$ such that $T$ has the following matrix form

$$
\left[\begin{array}{cc}
A^{c}(a) & \widehat{A}^{c}(b i) \\
\widehat{A}^{c}(b i) & A^{c}(a)
\end{array}\right] .
$$

Proof. Let $\left\{v_{1}, \cdots, v_{k}\right\}$ and $\left\{w_{1}, \cdots, w_{k}\right\}$ be a pair of Jordan bases as in Lemma 3.2. Since $\left\langle v_{i}, w_{j}\right\rangle=\left\langle v_{k}, w_{1}\right\rangle=1$ for $i+j=k+1$, the following form an orthonormal basis of $E_{p}$

$$
\begin{aligned}
a_{1} & =\frac{1}{2}\left(v_{1}+w_{k}\right), \quad a_{2}=\frac{1}{2}\left(v_{2}+w_{k-1}\right), \cdots \\
a_{k+1} & =\frac{1}{2}\left(v_{1}-w_{k}\right), \quad a_{k+2}=\frac{1}{2}\left(v_{2}-w_{k-1}\right), \cdots
\end{aligned}
$$

and the matrix of $T$ is given as above. (We note that $\left\|a_{1}\right\|=\cdots=\left\|a_{l}\right\|=1$ and $\left\|a_{l+1}\right\|=\cdots=\left\|a_{2 l}\right\|=-1$ ).

Finally in the most general case we obtain an orthonormal basis and construct the normal form of $T$ as follows: First decompose $E$ into the direct sum of pairwise orthogonal subspaces where each subspace is invariant under $T$ and the restriction of $T$ to a given subspace is a Jordan block. For each subspace form the orthonormal basis given by Propositions 3.1 or 3.2 accordingly, then rearrange these basis elements to construct an orthonormal basis by first listing the basis elements of norm one corresponding to the real eigenvalues followed by the basis elements of norm one corresponding to the complex eigenvalues. Then follow these by the basis elements of norm minus one corresponding first to the real and then to the complex eigenvalues. This result can be stated as
Theorem 3.3. Let $E$ be a pseudo-unitary space, and let $T$ be a self-adjoint linear transformation on $E$ with real eigenvalues $\alpha_{1}, \cdots, \alpha_{p}$ and complex eigenvalues $\lambda_{1}, \cdots, \lambda_{s}$ with $\lambda_{j}=a_{j}+b_{j} i$ and $b_{j}>0$. Then, there is an orthonormal basis $\beta$ for $E$ such that the transformation is represented by the following matrix with respect to $\beta$ :

$$
\left[\begin{array}{cccc}
e^{r} & & h^{r} & \\
& a^{c} & & (\widehat{a})^{c} \\
\left(h^{r}\right)^{*} & & g^{r} & \\
& (\widehat{a})^{c} & & a^{c}
\end{array}\right]
$$

Blocks with the superscript $c$ are associated with the complex eigenvalues, and blocks with the superscript $r$ are obtained from the real eigenvalues. Furthermore, using the notation of Propositions 3.1 and 3.2 each superscripted lower case letter is a block diagonal matrix whose structure is given by
(1) $e^{r}=\left(E^{r}\left(\alpha_{1}\right), \ldots, E^{r}\left(\alpha_{p}\right)\right)$ where:
$E^{r}\left(\alpha_{j}\right)=\left\{\begin{array}{cl}\left(A_{\epsilon}\right)^{r}\left(\alpha_{j}\right) & \text { if } k \text { is even; } \\ B^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is positive; } \\ A^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is negative } .\end{array}\right.$
(2) $h^{r}=\left(H^{r}\left(\alpha_{1}\right), \ldots, H^{r}\left(\alpha_{p}\right)\right)$ where: $H^{r}\left(\alpha_{j}\right)=\left\{\begin{array}{cl}\left(\widehat{A}_{\epsilon}\right)^{r} & \text { if } k \text { is even; } \\ \widehat{C}^{r} & \text { if } k \text { is odd and the sign characteristic is positive; } \\ \widehat{K}^{r} & \text { if } k \text { is odd and the sign characteristic is negative. }\end{array}\right.$
(3) $g^{r}=\left(G^{r}\left(\alpha_{1}\right), \ldots, G^{r}\left(\alpha_{p}\right)\right)$ where:
$G^{r}\left(\alpha_{j}\right)=\left\{\begin{array}{cl}\left(A_{-\epsilon}\right)^{r}\left(\alpha_{j}\right) & \text { if } k \text { is even; } \\ A^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is positive; } \\ L^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is negative } .\end{array}\right.$
(4) $a^{c}=\left(A^{c}\left(a_{1}\right), \ldots, A^{c}\left(a_{s}\right)\right)$.
(5) $(\widehat{a})^{c}=\left(\widehat{A}^{c}\left(b_{1} i\right), \ldots, \widehat{A}^{c}\left(b_{s} i\right)\right)$.

## 4. Self-adjoint linear transformations on a pseudo-euclidean space

In this section we consider a self-adjoint, linear transformation $T$, on a pseudoeuclidean space $V$. As in the complex case above, $V$ can be decomposed into the direct sum of invariant and pairwise orthogonal subspaces where the restriction of $T$ to each subspace has either a single real eigenvalue or a single pair of complex, conjugate eigenvalues. This again allows us to reduce the problem to two cases and to further decompose each subspace into the direct sum of invariant and pairwise orthogonal subspaces where the restriction of $T$ to each subspace is now either a real or a generalized real Jordan block. In the case of a complex eigenvalue, we first complexify the subspace and extend $T$ to the complexified subspace. We then use the Jordan basis constructed in Section 3 to obtain a real Jordan basis for the real subspace. We next modify this basis to obtain an orthonormal basis for this subspace. Finally, to obtain the orthonormal basis in the general case, we combine the basis elements for all the subspaces. Here, as in the complex case, we list all basis elements of norm-1 after the basis elements of norm 1, and obtain our normal form.

Similar to the complex case we have
Lemma 4.1. If $V_{1}$ and $V_{2}$ are eigenspaces of $T$ corresponding to real eigenvalues $\alpha_{1} \neq \alpha_{2}$, then $V_{1}$ and $V_{2}$ are orthogonal.

The next lemma shows that the null space corresponding to a complex eigenvalue of $T$ is orthogonal to the eigenspace corresponding to a real eigenvalue of $T$.

Lemma 4.2. Let $V_{1}=\left\{x \mid(T-\alpha I)^{m} x=0\right\}$ be the eigenspace of $T$ corresponding to the real eigenvalue $\alpha$, and let $\lambda$ and be a complex eigenvalue of $T$, and suppose that $\lambda$ is a root of the polynomial: $x^{2}+a x+b$. Let $V_{2}=\left\{y \mid\left(T^{2}+a T+b\right)^{n} y=0\right\}$ be the null space of $\left(T^{2}+a T+b\right)^{n}$. Then $V_{1}$ and $V_{2}$ are orthogonal.

Proof. Choose vectors $x \in V_{1}$ and $y \in V_{2}$. Then $(T-\alpha I)^{m} x=0$ and $\left(T^{2}+a T+b\right)^{n} y=0$. We use induction on $m+n$ to show that $\langle x, y\rangle=0$. For $m+n=1$ then either $x=0$ or $y=0$, and, hence, $\langle x, y\rangle=0$. For $m+n>1$, let $x_{1}=(T-\alpha I) x, x_{2}=(T-\alpha I)^{2} x$ and $y_{1}=\left(T^{2}+a T+b\right) y$. Then, using the induction hypothesis
(i) $\left\langle x_{1}, y\right\rangle=0$; This implies that $\langle T x, y\rangle=\alpha\langle x, y\rangle$
(ii) $\left\langle x_{2}, y\right\rangle=0$; This along with (i) implies that $\left\langle T^{2} x, y\right\rangle=\alpha^{2}\langle x, y\rangle$
(iii) Finally, $\left\langle x, y_{1}\right\rangle=0$. Then using the symmetry of T along with the results of (i) and (ii) we have

$$
\left(\alpha^{2}+a \alpha+b\right)\langle x, y\rangle=0
$$

For $\alpha$ real, $\alpha^{2}+a \alpha+b \neq 0$. Thus $\langle x, y\rangle=0$.

Complexification. To continue the rest of our construction, let $E=V+i V$ be the complexification of $V$. Then, $E$ is a pseudo-unitary space with the inner product defined by

$$
\left\langle x_{1}+i y_{1}, x_{2}+i y_{2}\right\rangle=\left(\left\langle x_{1}, x_{2}\right\rangle+\left\langle y_{1}, y_{2}\right\rangle\right)+\left(\left\langle y_{1}, x_{2}\right\rangle-\left\langle x_{1}, y_{2}\right\rangle\right) i .
$$

The transformation $T$ extends to a self-adjoint, linear transformation, which we again denote by $T$, via

$$
T(x+i y)=T x+i T y
$$

Note that considering $T$ either as a linear transformation on $V$ or as a linear transformation on the complexification $E$, it has the same eigenvalues. Next we prove that null spaces corresponding to distinct non-conjugate complex eigenvalues of $T$ are orthogonal.

Lemma 4.3. Let $\lambda=a+i b$ and $\gamma=c+i d$ be distinct, and non-conjugate, complex eigenvalues of T. Let

$$
V_{1}=\left\{x \mid\left[(T-a)^{2}+b^{2}\right]^{m} x=0\right\}
$$

and

$$
V_{2}=\left\{x^{\prime} \mid\left[(T-c)^{2}+d^{2}\right]^{n} x^{\prime}=0\right\}
$$

be subspaces of $V$. Then $V_{1}$ and $V_{2}$ are orthogonal.
Proof. Let $E_{1} \subseteq E$ be the sum of the eigenspaces corresponding to $\lambda$ and $\bar{\lambda}$. Similarly, let $E_{2} \subseteq E$ be the sum of the eigenspaces corresponding to $\gamma$ and $\bar{\gamma}$. We have $v=x+i y \in E_{1}$ if and only if $x, y \in V_{1}$ and $w=x^{\prime}+i y^{\prime} \in E_{2}$ if and only if $x^{\prime}, y^{\prime} \in V_{2}$. Since $\bar{v} \in E_{1}$ as well, we have $\langle v, w\rangle=0$ and $\langle\bar{v}, w\rangle=0$. This implies that $\langle x, y\rangle=0,\left\langle x^{\prime}, y\right\rangle=0,\left\langle x, y^{\prime}\right\rangle=0$, and $\left\langle x^{\prime}, y^{\prime}\right\rangle=0$, and thus proves the lemma.

The nondegeneracy of the inner product implies that complex eigenvalues of $T$ come in conjugate pairs, and therefore, we can state the following:

Proposition 4.1. Let $T$ be a self-adjoint, linear transformation on a pseudoeuclidean space $V$. Then $V$ can be decomposed into the direct sum of pairwise orthogonal, invariant subspaces, $V=V_{1}+V_{2}+\cdots+V_{s}$, where the restriction of $T$ to each $V_{i}$ has either a single real eigenvalue $\alpha$ or a pair of complex conjugate eigenvalues $\lambda$ and $\bar{\lambda}$.

Thus, we reduce our construction of an orthonormal basis to two cases.
Case I. T has a single real eigenvalue.
Similar to the case of a pseudo-unitary space we construct a special Jordan basis as follows:

Lemma 4.4. Let $T$ be a self-adjoint, linear transformation on a pseudoeuclidean space $V$ with a single real eigenvalue $\alpha$. Then $V=V_{1}+V_{2}+\cdots+V_{r}$ is the direct sum of orthogonal, invariant subspaces such that the restriction of
$T$ to each subspace produces a Jordan block. The Jordan basis, $\left\{x_{1}, \cdots, x_{k}\right\}$, for a subspace $V_{p}$, is chosen such that $\left\langle x_{i}, x_{j}\right\rangle=\left\langle x_{1}, x_{k}\right\rangle=\epsilon$ if $i+j=k+1$, where again $\epsilon= \pm 1$, is called the sign characteristic of the inner product on $E_{p}$ and $\left\langle x_{i}, x_{j}\right\rangle=0$ otherwise.
Proof. Choose $k$ such that $(T-\alpha I)^{k-1} \neq 0$ and $(T-\alpha I)^{k}=0$. Define $B(x, y)=\left\langle(T-\alpha I)^{k-1} x, y\right\rangle$. Since $T$ is self-adjoint, (and the inner product is non-degenerative) $B$ is a symmetric bilinear form on $V$ which is not identically zero. Thus there is an $x \in V$ such that $B(x, x)=r \neq 0$. By replacing $x$ with $\frac{x}{\sqrt{|r|}}$ if necessary we can assume that $B(x, x)=\epsilon$. Let $x_{1}=x, x_{p}=(T-\alpha I) x_{p-1}$ for $2 \leq p \leq k$. Then $\left\langle x_{i}, x_{j}\right\rangle=0$ if $i+j>k+1$ and $\left\langle x_{i}, x_{j}\right\rangle=\left\langle x_{1}, x_{k}\right\rangle=$ $B(x, x)= \pm 1$ if $i+j=k+1$. Replace $x_{1}$ with a suitable linear combination of $x_{1}, x_{2}, \cdots, x_{k}$ (as is necessary) to have $\left\langle x_{i}, x_{j}\right\rangle=0$ if $i+j \neq k+1$ and $\left\langle x_{i}, x_{j}\right\rangle=\left\langle x_{1}, x_{k}\right\rangle=\epsilon$ for $i+j=k+1$. Let $V_{1}=\operatorname{span}\left\{x_{1}, \cdots, x_{k}\right\}$. $V_{1}$ is invariant under $T$, and $\left\{x_{1}, \cdots, x_{k}\right\}$ is a Jordan basis. The restriction of $T$ to this subspace is a Jordan block. Decompose $V=V_{1}+V_{1}^{\perp}$ and repeat the same construction on $V_{1}^{\perp}$.

Proposition 4.2. Let $V_{p}$ be an invariant subspace of dimension $k$ with a single real eigenvalue $\alpha$ as in Lemma 4.4. Then, there is an orthonormal basis $\beta$ of $V_{p}$ such that the matrix of $T$ with respect to $\beta$ is:
a) for $k=2 l$ even

$$
\left[\begin{array}{cc}
\left(A_{\epsilon}\right)^{r}(\alpha) & \left({ }_{\epsilon} \widehat{D}\right)^{r} \\
\left({ }_{\epsilon} \widehat{D}^{r}\right)^{*} & \left(-\epsilon A^{r}\right)(\alpha)
\end{array}\right],
$$

(Each square block is of dimension l.) where again $\epsilon= \pm 1$.
b) for $k=2 l+1$ odd and the sign characteristic is positive

$$
\left[\begin{array}{cc}
B^{r}(\alpha) & \widehat{N}^{r} \\
\left(\widehat{N}^{r}\right)^{*} & A^{r}(\alpha)
\end{array}\right]
$$

$\left(A^{r}(\alpha)\right.$ and $B^{r}(\alpha)$ are square matrices of dimensions $l$ and $l+1$ respectively).
c) for $k=2 l+1$ odd and the sign characteristic is negative

$$
\left[\begin{array}{cc}
A^{r}(\alpha) & \widehat{E}^{r} \\
\left(\widehat{E}^{r}\right)^{*} & M^{r}(\alpha)
\end{array}\right] .
$$

$\left(A^{r}(\alpha)\right.$ and $M^{r}(\alpha)$ are square matrices of dimension $l$ and $l+1$ respectively).

Proof.
(1) If $k=2 l$ is even, and the sign characteristic is positive, then let

$$
a_{1}=\frac{1}{\sqrt{2}}\left(x_{1}+x_{2 l}\right), \quad a_{2}=\frac{1}{\sqrt{2}}\left(x_{2}+x_{2 l-1}\right), \cdots, \quad a_{l}=\frac{1}{\sqrt{2}}\left(x_{l}+x_{l+1}\right)
$$

$$
a_{2 l}=\frac{1}{\sqrt{2}}\left(x_{1}-x_{2 l}\right), \quad a_{2 l-1}=\frac{1}{\sqrt{2}}\left(x_{2}-x_{k-1}\right), \cdots, a_{l+1}=\frac{1}{\sqrt{2}}\left(x_{l}-x_{l+1}\right) .
$$

The set $\left\{a_{i}\right\}, 1 \leq i \leq 2 l$, form the orthonormal basis. If the sign characteristic is negative then replace $a_{i}$ by $a_{2 l+1-i}$ and viceversa for $1 \leq i \leq l$.
(2) If $k=2 l+1$ is odd and the sign characteristic is positive, let

$$
\begin{gathered}
a_{1}=\frac{1}{\sqrt{2}}\left(x_{1}+x_{2 l+1}\right), \quad a_{2}=\frac{1}{\sqrt{2}}\left(x_{2}+x_{2 l}\right), \cdots, a_{l}=\frac{1}{\sqrt{2}}\left(x_{l}+x_{l+2}\right) \\
a_{l+1}=x_{l+1} \\
a_{2 l+1}=\frac{1}{\sqrt{2}}\left(x_{1}-x_{2 l+1}\right), \quad a_{2 l}=\frac{1}{\sqrt{2}}\left(x_{2}-x_{2 l}\right), \cdots, a_{l+2}=\frac{1}{\sqrt{2}}\left(x_{l}-x_{l+2}\right) .
\end{gathered}
$$

If the sign characteristic is negative then replace $a_{i}$ by $a_{2 l+2-i}$ and viceversa for $1 \leq i \leq l$.

Case II. T has a single pair of complex conjugate eigenvalues.
The following derivation of the real Jordan form, (see [7]), will help us to construct the orthonormal basis in Proposition 4.3.

Lemma 4.5. Let $T$ be a self-adjoint, linear transformation on a pseudoeuclidean space $V$ with $\lambda=a+b i$ and $\bar{\lambda}=a-b i$ the only eigenvalues. Then, $V=V_{1}+\cdots+V_{r}$ is the direct sum of orthogonal, invariant subspaces, and the matrix of $T$ when restricted to each subspace produces a "generalized real Jordan block" of the form

$$
\left[\begin{array}{ccccccccc}
a & b & & & & & & & \\
-b & a & & & & & & & \\
1 & 0 & a & b & & & & & \\
0 & 1 & -b & a & & & & & \\
& & 1 & 0 & a & b & & & \\
& & 0 & 1 & -b & a & & & \\
& & & & \ddots & & \ddots & & \\
& & & & & 1 & 0 & a & b \\
& & & & & 0 & 1 & -b & a
\end{array}\right] .
$$

Proof. Let $E$ be the complexification of $V$. Choose $k$ such that $(T-\lambda I)^{k}=0$ and $(T-\lambda I)^{k-1} \neq 0$. Consider $B(v, w)=\left\langle(T-\lambda I)^{k-1} v, \bar{w}\right\rangle$. Since $T$ is selfadjoint, $B$ is Hermitian, and because the inner product is non-degenerate it is not identically zero, and so we can choose $v^{\prime}$ such that $B\left(v^{\prime}, v^{\prime}\right)=\zeta \neq 0$. Let
$v=\frac{v^{\prime}}{\sqrt{\zeta}}$. Then

$$
\begin{aligned}
B(v, v) & =B\left(\frac{v^{\prime}}{\sqrt{\zeta}}, \frac{v^{\prime}}{\sqrt{\zeta}}\right)=\left\langle(A-\lambda I)^{k-1} \frac{v^{\prime}}{\sqrt{\zeta}}, \frac{\overline{v^{\prime}}}{\sqrt{\zeta}}\right\rangle \\
& =\frac{1}{\zeta}\left\langle(A-\lambda I)^{k-1} v^{\prime}, \overline{v^{\prime}}\right\rangle=\frac{\zeta}{\zeta}=1 .
\end{aligned}
$$

Thus, in the proof of Lemma 3.2 we can choose $w=\bar{v}$ and decompose $E$ into the direct sum of orthogonal, invariant subspaces, i.e., $E=E_{1}+E_{2}+\cdots+E_{r}$, where the restriction of T to each subspace produces a pair of Jordan blocks. For example, the Jordan basis chosen for $E_{p}$ is

$$
\begin{aligned}
& v_{1}=v, \quad v_{i}=(T-\lambda I) v_{i-1} \\
& w_{1}=\bar{v}, w_{i}=(T-\bar{\lambda}) w_{i-1}=\bar{v}_{i}, \quad 2 \leq i \leq k
\end{aligned}
$$

and

$$
\begin{gathered}
\left\langle v_{i}, v_{j}\right\rangle=\left\langle\bar{v}_{i}, \bar{v}_{j}\right\rangle=0 \quad \text { for all } i, j, \\
\left\langle v_{i}, \bar{v}_{j}\right\rangle=1 \quad \text { for } i+j=k+1, \\
\left\langle v_{i}, \bar{v}_{j}\right\rangle=0 \quad \text { for } i+j \neq k+1
\end{gathered}
$$

Now let $v_{j}^{r}=\frac{1}{2}\left(v_{j}+\bar{v}_{j}\right)$ and $v_{j}^{c}=\frac{1}{2 i}\left(v_{j}-\bar{v}_{j}\right)$. Then

$$
\beta=\left\{v_{1}^{r}, v_{1}^{c}, v_{2}^{r}, v_{2}^{c}, \cdots, v_{k}^{r}, v_{k}^{c}\right\}
$$

form a real Jordan basis for $V_{1}$, a subspace of $V$, and the matrix of $T$ with respect to $\beta$ is as claimed.
Proposition 4.3. Let $V_{p}$ be an invariant subspace with a single pair of complex eigenvalues, $\lambda=a+b i$ and $\bar{\lambda}=a-b i$ with $b>0$ as in Lemma 4.5, and assume it is of dimension $2 k$. Then there is an orthonormal basis $\beta$ of $V_{p}$ such that the matrix of $T$ with respect to $\beta$ is
a) for $k=2 l$ even

$$
\left[\begin{array}{cc}
W^{c}(a) & Y^{c}(b) \\
\left(Y^{c}(b)\right)^{*} & W^{c}(a)
\end{array}\right]
$$

where
$W^{c}(a)=\left[\begin{array}{ll}\left(A_{1}\right)^{c}(a) & \\ & \left(A_{-1}\right)^{c}(a)\end{array}\right] \quad Y^{c}(b)=\left[\begin{array}{cc}b I_{l} & \left(-\widehat{A}_{1}\right)^{c} \\ \left(\left(-\widehat{A}_{1}\right)^{c}\right)^{*} & -b I_{l}\end{array}\right]$.
b) for $k=2 l+1$ odd

$$
\left[\begin{array}{cc}
P^{c}(a) & Q^{c}(b) \\
\left(Q^{c}(b)\right)^{*} & P^{c}(a)
\end{array}\right]
$$

where

$$
P^{c}(a)=\left[\begin{array}{cc}
B^{c}(a) & \\
& A^{c}(a)
\end{array}\right] \quad Q^{c}(b)=\left[\begin{array}{cc}
b I_{l+1} & -\widehat{C}^{c} \\
\left(-\widehat{C}^{c}\right)^{*} & -b I_{l}
\end{array}\right] .
$$

Proof. Notice that $\left\langle v_{i}, \bar{v}_{j}\right\rangle=1$ for $i+j=k+1$. This implies that $\left\langle v_{i}^{r}, v_{j}^{r}\right\rangle-$ $\left\langle v_{i}^{c}, v_{j}^{c}\right\rangle=1$. Similarly, since $\left\langle v_{i}, v_{j}\right\rangle=0$, we get $\left\langle v_{i}^{r}, v_{j}^{r}\right\rangle+\left\langle v_{i}^{c}, v_{j}^{c}\right\rangle=0$. Thus

$$
\left\langle v_{i}^{r}, v_{j}^{r}\right\rangle=\frac{1}{2} \quad \text { and } \quad\left\langle v_{i}^{c}, v_{j}^{c}\right\rangle=-\frac{1}{2} \quad \text { for } \quad i+j=k+1
$$

Again, from $\left\langle v_{i}, v_{j}\right\rangle=0$, we have

$$
\left\langle v_{i}^{c}, v_{j}^{r}\right\rangle=\left\langle v_{i}^{r}, v_{j}^{c}\right\rangle=0 \quad \text { for all } \quad i, j,
$$

and

$$
\left\langle v_{i}^{r}, v_{j}^{r}\right\rangle=\left\langle v_{i}^{c}, v_{j}^{c}\right\rangle=0 \quad \text { if } \quad i+j \neq k+1 .
$$

We construct an orthonormal basis, $\beta$, as follows:
Case A: $k=2 l$ is even, i.e., $\operatorname{dim}(V)=4 l$. Let

$$
\begin{gathered}
x_{1}=v_{1}^{r}+v_{2 l}^{r}, \quad x_{2}=v_{2}^{r}+v_{2 l-1}^{r}, \cdots, x_{l}=v_{l}^{r}+v_{l+1}^{r}, \\
x_{l+1}=-v_{1}^{c}+v_{2 l}^{c}, \quad x_{l+2}=-v_{2}^{c}+v_{2 l-1}^{c}, \cdots, x_{2 l}=-v_{l}^{c}+v_{l+1}^{c}, \\
x_{2 l+1}=v_{1}^{c}+v_{2 l}^{c}, \quad x_{2 l+2}=v_{2}^{c}+v_{2 l-1}^{c}, \cdots, x_{3 l}=v_{l}^{c}+v_{l+1}^{c} \\
x_{3 l+1}=-v_{1}^{r}+v_{2 l}^{r}, \quad x_{3 l+2}=-v_{2}^{r}+v_{2 l-1}^{r}, \cdots, x_{4 l}=-v_{l}^{r}+v_{l+1}^{r} .
\end{gathered}
$$

Case B: $k=2 l+1$ odd, i.e., $\operatorname{dim}(V)=4 l+2$. Then the orthonormal basis is

$$
\begin{gathered}
x_{1}=v_{1}^{r}+v_{2 l+1}^{r}, \quad x_{2}=v_{2}^{r}+v_{2 l}^{r}, \cdots, x_{l}=v_{l}^{r}+v_{l+2}^{r}, \\
x_{l+1}=\sqrt{2} v_{l+1}^{r}, \\
x_{l+2}=-v_{1}^{c}+v_{2 l+1}^{c}, \cdots, x_{2 l+1}=-v_{l}^{c}+v_{l+2}^{c}, \\
x_{2 l+2}=v_{1}^{c}+v_{2 l+1}^{c}, \cdots, x_{3 l+1}=v_{l}^{c}+v_{l+2}^{c}, \\
x_{3 l+2}=\sqrt{2} v_{l+1}^{c}, \\
x_{3 l+3}=-v_{1}^{r}+v_{2 l+1}^{r}, \cdots, x_{4 l+2}=-v_{l}^{r}+v_{l+2}^{r} .
\end{gathered}
$$

Finally, when $T$ has several eigenvalues, as in the complex case above, we decompose $V$ into the direct sum of pairwise, orthogonal subspaces such that each subspace is invariant under the transformation $T$ and the restriction of $T$ to each subspace is given by a Jordan block. We use Propositions 4.2 and 4.3 accordingly to construct the orthonormal basis on each subspace and form an orthonormal basis for $V$ by listing all the basis elements of norm -1 after listing the basis elements of norm +1 .
Theorem 4.4. Let $V$ be a pseudo-euclidean space, and let $T$ be a self-adjoint linear transformation on $V$ with real eigenvalues $\alpha_{1}, \cdots, \alpha_{p}$ and complex eigenvalues $\lambda_{1}, \cdots, \lambda_{s}$ with $\lambda_{j}=a_{j}+b_{j} i$ and $b_{j}>0$. Then, there is an orthonormal basis $\beta$ for $E$ such that the transformation is represented by the following matrix with respect to $\beta$ :

$$
\left[\begin{array}{cccc}
e^{r} & & h^{r} & \\
& a^{c} & & (\widehat{a})^{c} \\
\left(h^{r}\right)^{*} & & g^{r} & \\
& (\widehat{a})^{c} & & a^{c}
\end{array}\right]
$$

Blocks with the superscript c are associated with the complex eigenvalues, and blocks with the superscript $r$ are obtained from the real eigenvalues.

Furthermore, using the notation of Propositions 4.2 and 4.3 each superscripted lower case letter is a block diagonal matrix whose structure is given by
(1) $e^{r}=\left(E^{r}\left(\alpha_{1}\right), \cdots, E^{r}\left(\alpha_{p}\right)\right)$ where:
$E^{r}\left(\alpha_{j}\right)=\left\{\begin{array}{cl}\left(A_{\epsilon}\right)^{r}\left(\alpha_{j}\right) & \text { if } k \text { is even; } \\ B^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is positive; } \\ A^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is negative. }\end{array}\right.$
(2) $h^{r}=\left(H^{r}\left(\alpha_{1}\right), \cdots, H^{r}\left(\alpha_{p}\right)\right)$ where:
$H^{r}\left(\alpha_{j}\right)=\left\{\begin{array}{cl}\left({ }_{\epsilon} \widehat{D}\right)^{r} & \text { if } k \text { is even } ; \\ \widehat{N}^{r} & \text { if } k \text { is odd and the sign characteristic is positive; } \\ \widehat{E}^{r} & \text { if } k \text { is odd and the sign characteristic is negative } .\end{array}\right.$
(3) $g^{r}=\left(G^{r}\left(\alpha_{1}\right), \cdots, G^{r}\left(\alpha_{p}\right)\right)$ where:
$G^{r}\left(\alpha_{j}\right)=\left\{\begin{array}{cl}-\epsilon\left(A^{r}\right)\left(\alpha_{j}\right) & \text { if } k \text { is even; } \\ A^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is positive; } \\ M^{r}\left(\alpha_{j}\right) & \text { if } k \text { is odd and the sign characteristic is negative } .\end{array}\right.$
(4) $a^{c}=\left(U^{c}\left(a_{1}\right), \cdots, U^{c}\left(a_{s}\right)\right)$ where:

$$
U^{c}\left(a_{j}\right)= \begin{cases}W^{c}\left(a_{j}\right) & \text { if } k \text { is even } \\ P^{c}\left(a_{j}\right) & \text { if } k \text { is odd } .\end{cases}
$$

(5) $(\widehat{a})^{c}=\left(V^{c}\left(b_{1}\right), \ldots, V^{c}\left(b_{s}\right)\right)$ where:

$$
V^{c}\left(b_{j}\right)= \begin{cases}Y^{c}\left(b_{j}\right) & \text { if } k \text { is even }, \\ Q^{c}\left(b_{j}\right) & \text { if } k \text { is odd } .\end{cases}
$$
